

Lecture review

Stack and Queue

Stack and *queue* are two important ADTs. A stack stores items in a last-in, first-out (LIFO) manner, whereas a queue stores items in a first-in, first-out (FIFO) manner. Following table summarizes the operations of a stack and a queue.

Stack	Queue	Description
<code>push(x)</code>	<code>enqueue(x)</code>	Insert an item x
<code>pop()</code>	<code>dequeue()</code>	Remove and return an item (most recently inserted item for stack and least recently inserted one for queue)
<code>empty()</code>	<code>empty()</code>	Return true if the stack/queue is empty
<code>size()</code>	<code>size()</code>	Return the number of items in the stack/queue

We have seen two implementations of stacks and queues in the lecture: **RAStack** and **RAQueue** using *resizable arrays*, and similarly **LLStack** and **LLQueue** using *linked lists*. Note that from the perspective of the user, the two implementations of stack (respectively queue) are indistinguishable as both provide the identical public interface. The following files are provided for your reference:

- `ra_stack.cpp` and `ll_stack.cpp` implement a stack using resizable array and linked list respectively.
- `ra_queue.cpp` and `ll_queue.cpp` implement a queue using resizable array and linked list respectively.

Copy constructor: Shallow vs Deep copy

A *copy constructor* is a special constructor that initializes a new object from an existing object. It is used to create a new object as a copy of an existing object. When copying objects that contain pointers, (as the above implementations of stack and queue do), we need to be careful about how we want to make a copy. For instance, consider the class **RAStack** that contains a pointer `arr` to an array of strings. The copy constructor of **RAStack** can be implemented in following two ways:

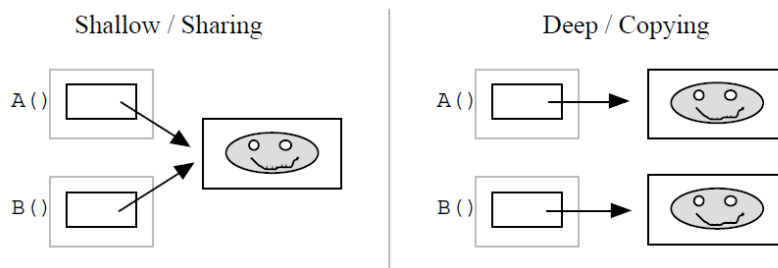

```
RAStack(const RASTack& rhs)
: arr(rhs.arr),
  sz(rhs.sz),
  cap(rhs.cap) {
}
```

```
RAStack(const RASTack& rhs)
: arr(new string[rhs.cap]),
  sz(rhs.sz),
  cap(rhs.cap) {
  for (int i = 0; i < sz; ++i)
    arr[i] = rhs.arr[i];
}
```

On the left is the *shallow copy* implementation of the copy constructor, and on the right is the *deep copy* implementation. By shallow copy, we mean that the copy constructor copies the pointer but not the object that the pointer points to. Whereas deep copy mean that the copy constructor allocate a new array and copies the elements of the array pointed to by `rhs.arr` to the new array.

Note that with shallow copy, the two objects ***this** and **rhs** will share the same array. So if we modify the array of one object, the other object will also be affected. This is not the case with deep copy as both stack objects will have their own copy of the array. So naturally, deep copy is more expensive than shallow copy as it involves allocating a new array and copying the elements of the array. But it is also safer as the two objects will not share the same array.

Following figure illustrates the difference between shallow and deep copy:

Assignment operator

The assignment operator is used to assign a new value to an existing variable. The operator can be overloaded to provide a specific implementation of the assignment for a class. For instance, consider the following implementation of the assignment operator for **RASStack**:

```
RASStack& operator=(const RASStack& rhs) {
    if (this != &rhs) {
        delete[] arr;
        arr = new string[rhs.cap];
        sz = rhs.sz;
        cap = rhs.cap;
        for (int i = 0; i < sz; ++i)
            arr[i] = rhs.arr[i];
    }
    return *this;
}
```

The concept of shallow and deep copy also applies to the assignment operator. The above implementation of the assignment operator is a deep copy implementation.

Lab exercises

revise Class and Object concepts

Exercise 1

Create a class called Pair that has two public integer member variables named "a" and "b", and a public member function named sum() that has no arguments but adds the two member variables together and returns their sum.

Exercise 2

Kristen is a contender for valedictorian of her high school. She wants to know how many students (if any) have scored higher than her in the 5 exams given during this semester. Create a class named Student with the following specifications:

- I An instance variable named Scores to hold a student's exam scores.
- II A void input () function that reads 5 integers and saves them to Scores.
- III An int calculateTotalScore() function that returns the sum of the student's scores.

Access Modifiers

Exercise 3

Write a program in which a class named Account has private member variables named account_no, account_bal, security_code. Use a public function to initialize the variables and print all data.

Static and Constant

Exercise 4

To count the object value using the storage keyword static.

Write a program of your own in which you demonstrate the concept of constant keyword.

Exercise 5

you are given a task by your instructor in which he asked you to write a program which can take two sides, radius, base and angle as input for a class with name Draw. Then write three more subclasses with name drawRectangle, drawRhombus and drawCircle, that is for finding the area of Rectangle and area of circle and area of Rhombus. In driver function define three variables with name drawRectangle, drawCircle and drawRhombus which can call the area function for the private variables side1, side2, radius, base and angle of Draw class. (The name of function finding area() will remain same in all child classes). Hint: (use trigonometric formula)

```
Enter value for Rectangle side1: 5
Enter value for Rectangle side2: 6
Enter value for radius: 7
Enter value for Rhombus base: 4
Enter value for Rhombus angle: 90

Area of Rectangle is: 30
Area of Circle is: 153.86
Area of Rhombus is: 14.3039
```

Figure 1: Sample Output

Exercise 6

Write a program with a name father and a subclass with name son. Both of them should have a function with same name but different body. In driver function define a son and call the on it.

Exercise 7

Write down a program which asks you your name, age, std_id, gender, your marks earned in programming fundamentals, your remaining courses marks as input and display your entered information as output on the screen along with your grades in each subject and gpa and total cgpa as well. Formula for calculating gpa and cgpa is given below.

```
GPA= Sum of (Credit*Point) / total of credits
CGPA= Sum of GPA / number of semesters
```

Figure 2: Sample Output

[Stack and Copy Constructor](#)**Exercise 8**

Write a Stack client that reads a string of parentheses, square brackets, and curly braces from standard input and uses a stack to determine whether they are properly balanced. For example, your program should print true for `[]{}{[(())]}()` and false for `[]()`.

Exercise 9

Josephus problem. In the *Josephus problem* from antiquity, n people are in dire straits and agree to the following strategy to reduce the population. They arrange themselves in a circle (at positions numbered from 0 to $n - 1$) and proceed around the circle, eliminating every m -th person until only one person is left. Legend has it that Josephus figured out where to sit to avoid being eliminated.

Write a Queue client that takes two integer inputs m and n and prints the order in which people are eliminated (and thus would show Josephus where to sit in the circle).

- *Example 1:*

Input: $n = 5$ and $m = 2$

Output: The safe position is 2

Explanation: Firstly, the person at position 1 is killed, then person at position 3 is killed, then person at position 0 is killed. Finally, the person at position 4 is killed. So the person at position 2 survives.

- *Example 2:*

Input: $n = 7$ and $m = 3$

Output: The safe position is 3

Explanation: The persons at positions 2, 5, 1, 6, 4, 0 are killed in order, and the person at position 3 survives.

Solution: We use a queue to store the positions of the people. Do $m - 1$ times: dequeue the a person from the queue and enqueue it back at the end of the queue. Next person at front of queue is to be killed. We repeat this process until only one person is left in the queue.

Exercise 10

Reverse a linked list. Write a function that takes the first **Node** in a linked list as an argument, and reverses the list, returning the first **Node** in the result.

Solution: To accomplish this, we maintain references to three consecutive nodes in the linked list, **reverse**, **first**, and **second**. At each iteration we extract the node first from the original linked list and insert it at the beginning of the reversed list. We maintain the invariant that **first** is the first node of what's left of the original list, **second** is the second node of what's left of the original list, and **reverse** is the first node of the resulting reversed list.

**Exercise 11**

Copy constructor for a stack. Create a new constructor for class **LLStack** (linked-list implementation of stack) so that **LLStack t {s};** makes **t** reference a new and independent copy of the stack **s**. That is, a deep copy of linked list pointed by **s.first** and make **t.first** point to the new list.

With deep copy, you should be able to push and pop from either **s** or **t** without influencing the other.

**Exercise 12**

Write a recursive function to print a linked list in reverse order. You may not use any loops or iteration.

Exercise 13

A palindrome is a word, phrase, number, or other sequence of characters which reads the same backwards and forwards. Can you determine if a given string, **s**, is a palindrome?

To solve this problem, you must first take each character in **s**, enqueue it in a queue, and also push that same character onto a stack. Once that's done, we must dequeue the first character from the queue and pop the top character off the stack, then compare the two characters to see if they are the same; as long as the characters match, we continue dequeuing, popping, and comparing each character until our containers are empty (a non-match means **s** isn't a palindrome).

Write the following declarations and implementations:

Two instance variables: one for your **stack** , and one for your **queue** .

A void **pushCharacter(char ch)** method that pushes a character onto a stack.

A void **enqueueCharacter(char ch)** method that enqueues a character in the queue instance variable.

A char **popCharacter()** method that pops and returns the character at the top of the stack instance variable.

A char **dequeueCharacter()** method that dequeues and returns the first character in the queue instance variable.

Figure 3: Sample Output
