

Business Administration CSE142 OBJECT ORIENTED PROGRAMMING TECHNIQUES Karachi Udeas for Tomorrow Spring '24

Lab #3 Jan 26, 2024

Lecture review

A **class** in C++ can be used to implement an abstract data type (ADT). As discussed in lecture, the first step in designing an ADT is to decide upon the API i.e., the set of operations that can be performed on the data. The next step is to decide upon the representation of the data. The instance variables (also called attributes) of the class are used to represent the data. The representation of the data is hidden from the user of the ADT. The user can only access the data through the operations defined in the API. This is called data encapsulation or information hiding. The attributes and methods of a class are collectively called the members of the class.

A constructor is a special method that is used to initialize objects. It is called when an object of a class is created. It can be used to set initial values for object attributes. It can also be used to perform any other initialization tasks required when an object is created. A constructor is defined like a method, except that it has the same name as the class and has no return type. For example, the following constructors can be defined for a class implementing rational numbers.

- A default constructor that initializes the numerator to 0 and the denominator to 1.
- A constructor that takes a single integer argument and initializes the numerator to that value and the denominator to 1.
- A constructor that takes two integer arguments and initializes the numerator and denominator to those values.
- A copy constructor that takes a rational object as an argument and initializes the numerator and denominator to the values of the corresponding attributes of the argument object.

The following code shows the definitions of the four overloaded constructors described above.

```
class Rational {
    private:
    int num, den;

public:
    // default constructor
    Rational() : num {0}, den {1} { /* empty */ }

Rational(int n) : num {n}, den {1} { /* empty */ }

Rational(int n, int d) : num {n}, den {d} { /* empty */ }

// copy constructor
    Rational(const Rational& r) : num {r.num}, den {r.den} { /* empty */ }
};
```

Exercise 1

Create an Account class that a bank might use to represent customers bank accounts. Include a data member to represent the account balance. Provide three member functions. Member function credit should add an amount to the current balance. Member function debit should withdraw money from the Account. Member function get Balance should return the current balance.

Exercise 2

Create a class called Invoice that a hardware store might use to represent an invoice for an item sold at the store. An Invoice should include four data members a part number, a part description, a quantity of the item being purchased and a price per item.

Exercise 3

A book shop maintains the inventory of books that are being sold at the shop. The list includes details such as author, title, price, publisher and stock position. Whenever a customer wants a book, the sales person inputs the title and author and the system searches the list and displays whether it is available or not. If it is not, an appropriate message is displayed. If it is, then the system displays the book details and requests for the number of copies required. If the requested copies are available, the total cost of the requested copies is displayed; otherwise "Required copies not in stock" is displayed. Design a system using a class called books with suitable member functions and constructors.

Exercise 4

Write a class called CoffeeShop, which has three instance variables:

- Name: a string (basically, of the shop)
- Menu: an array of items (of type MenuItem), with each item containing the item (name of the item), type (whether a food or a drink) and price.
- Orders: an empty array and seven methods:
- addOrder: adds the name of the item to the end of the orders array if it exists on the menu. Otherwise, return "This item is currently unavailable!"
- fulfillOrder: if the orders array is not empty, return "The item is ready!". If the orders array is empty, return "All orders have been fulfilled!"
- listOrders: returns the list of orders taken, otherwise, an empty array.
- dueAmount: returns the total amount due for the orders taken.
- cheapestItem: returns the name of the cheapest item on the menu.
- \bullet drinks Only: returns only the item names of type drink from the menu.
- foodOnly: returns only the item names of type food from the menu.

Exercise 5

Your task is to create a Circle constructor that creates a circle with a radius provided by an argument. The circles constructed must have two getters getArea() (πr^2) and getPerimeter() $2\pi r$ which give both respective areas and perimeter (circumference).

Exercise 6

In this exercise, you will improve the class Rational defined in previous section by adding more methods. First, add the following constructors to the class Rational.

- A constructor that takes a **string** argument and initializes the numerator and denominator to the values specified in the string. For example, the string "3/4" should initialize the numerator to 3 and the denominator to 4.
- A constructor that takes a floating point number as an argument and initializes the numerator and denominator to the closest rational number to the argument. For example, the floating point number 0.75 should initialize the numerator to 3 and the denominator to 4.

Furthermore, add the following methods to the class Rational. Note that some of the following methods are declared as **const**, which means that the method does not modify the object on which it is called.

Method	Description
<pre>int get_num()const</pre>	Returns the numerator of the rational number.
<pre>int get_den()const</pre>	Returns the denominator of the rational number.
<pre>void set_num(int n)</pre>	Sets the numerator of the rational number to n .
<pre>void set_den(int d)</pre>	Sets the denominator of the rational number to d .
string to_string()const	Converts the rational number to string in the form "num/den".
<pre>void reduce()</pre>	Reduces the rational number to its lowest terms. For example, if the rational number is $4/6$, then it should be reduced to $2/3$.
Rational operator +(const Rational& r) const	Returns the sum of the current rational number and the rational number ${\sf r}$ passed as an argument. The result should be in reduced form.
Rational operator -(const Rational& r) const	Returns the difference of the current rational number and the rational number ${\sf r}$ passed as an argument. The result should be in reduced form.
Rational operator *(const Rational& r) const	Returns the product of the current rational number and the rational number ${\sf r}$ passed as an argument. The result should be in reduced form.
Rational operator /(const Rational& r) const	Returns the quotient of the current rational number and the rational number r passed as an argument. The result should be in reduced form.
<pre>bool operator==(const Rational& r)const</pre>	Returns true if the current rational number is equal to the rational number r passed as an argument, and false otherwise. (Rational(1, 2)== Rational(2, 4) should return true)
<pre>bool operator!=(const Rational& r)const</pre>	Returns true if the current rational number is not equal to the rational number r passed as an argument, and false otherwise.

Write a client program that tests all the methods of the class Rational.

Exercise 7

TicTacToe: Create a **class TicTacToe** that will enable you to write a complete program to play the game of tic-tac-toe. The class contains as private data a 3-by-3 two-dimensional array of integers. The constructor should initialize the empty board to all zeros. Allow two human players. Wherever the first

player moves, place a 1 in the specified square. Place a 2 wherever the second player moves. Each move must be to an empty square.

The class should have the following public methods.

Method	Description
TicTacToe()	Default constructor. Initialize the board to all zeros.
<pre>void clearBoard()</pre>	Clear the board to all zeros.
<pre>void to_string()const</pre>	Return a string representation of the current board.
<pre>int gameStatus()const</pre>	Returns 1 or 2 if the player 1 or 2 wins respectively, 3 if the game is draw, and 0 if the game is not over yet.
<pre>bool move(int player, int row, int col)</pre>	Play a move for the player player at the row row and column col. Returns true if the move is successful, and false if the square is not empty.

If you feel ambitious, add a method **void** autoMove(int player) so that the computer makes the moves for player.

Write a client that runs a complete game of tic-tac-toe. Allow the two players to alternatively make the moves. After each move, determine whether the game has been won or is a draw. Following is a sample run of the program:

Welcome to Tic-Tac-Toe!

```
Play 2 move: enter row and column: 1 1

1 | 0 | 0

-----
0 | 2 | 0

-----
0 | 0 | 0
```

Play 1 move: enter row and column: 0 1

1 | 1 | 0

0 | 2 | 0

0 | 0 | 0

Play 2 move: enter row and column: 1 2

1 | 1 | 0

0 | 2 | 2

0 | 0 | 0

Play 1 move: enter row and column: 0 2

1 | 1 | 1

0 | 2 | 2

.

0 | 0 | 0

Player 1 wins!

Exercise 8

Create class IntegerSet for which each object can hold integers in the range 0 through 100. Represent the set internally as a vector of **bool** values. Element a[i] is **true** if integer i is in the set. Element a[j] is **false** if integer j is not in the set.

The default constructor initializes a set to the so-called "empty set," i.e., a set for which all elements contain **false**.

- Provide member functions for the common set operations. For example, provide a unionOfSets member function that creates a third set that is the set-theoretic union of two existing sets (i.e., an element of the result is set to **true** if that element is **true** in either or both of the existing sets, and an element of the result is set to **false** if that element is **false** in each of the existing sets).
- Provide an intersectionOfSets member function which creates a third set which is the settheoretic intersection of two existing sets (i.e., an element of the result is set to **false** if that element is **false** in either or both of the existing sets, and an element of the result is set to **true** if that element is true in each of the existing sets).
- Provide an insertElement member function that places a new integer k into a set by setting a[k] to true. Provide a deleteElement member function that deletes integer m by setting a[m] to false.
- Provide a to_string member function that returns a set as a string containing a list of numbers separated by spaces. Include only those elements that are present in the set (i.e., their position in the vector has a value of true). Return empty string "" for an empty set.
- Provide an isEqualTo member function that determines whether two sets are equal.
- Provide an additional constructor that receives an array of integers, and uses the array to initialize a set object.

Now write a driver program to test your IntegerSet class. Instantiate several IntegerSet objects. Test that all your member functions work properly.
